

Week 8

Day 39
13 Jul
Mon

Today, I focused on backend development using Node.js, express & mysql2 package. Then I created an API to perform CRUD operations on table or db's, like inserting, updating, deleting & displaying student records. I also used some error handling like try-catch block. Tested almost all api endpoints like GET, PUT, DELETE, POST using postman. and also did routing.

Test the API in postman and check whether all operations works or not.

Day 40
14 Jul
Tue

Today, I created an express server connected to 'authorization' db using mysql2 package. First I implemented registration & login endpoints to handle basic authorization. Then I created another api for products to perform CRUD operations and also to filter out products based on quantity or category.

Create server & api for products to perform CRUD operations.

Day 41
15 Jul
Wed

Today, we learned about React & created a normal webpage using components and learnt about how to export and import components from different file.

Create product cards using props (multiple) to show product cards.

Then we learned how to use parameters for components using props and also how to use multiple props in components, and also used variables for showing details.

Then they allotted us some work to create pages to show add, sub, div operations on variables and also a student component using multiple props.

Day 42
16 Jul
Thu

Today, we moved on routing in react using react-router-dom and its components like Route, Routes, BrowserRouter and Link. Link is like anchor tag in HTML. We created three to four web pages and linked them through `<BrowserRouter>` to App.js and performed routing which is done perfectly.

Use useState and create given pages.

Then we learned about `useState` to set some values or properties dynamically, or used to set value. Then we used `useState` to create counter the clicks and changing colors using it.

Day 43
17 Jul
Fri

Today we created a simple web application ~~using~~ including frontend plus backend using database (xampp), cors and multer for images, express mysql2 for db access. and for frontend axios, react-router-dom. Created two tables for products & users and then accessed that in backend wrote code for login, register, add product and logout and also add that endpoints for frontend for routing. Whenever someone login or register it checks that this email and password exists or not, based on that it redirects.

Fix the ui add css to make UI better and try to add validations.

Day 44

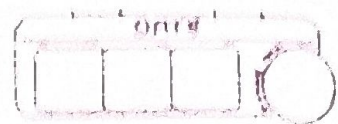

* 18 Jul

Sat

Today, sir taught us how to use validations in that project while registering or logging in. Today, applied validation for name so that it can't be empty and then applied for email that it must contain '@' and for password used limits of password can't be less than 6 characters and for login already had validations.

Apply validation for login and registration.

Week 9

	Discussion Topics & Activity	Details of work allotted till next sess
Day 45 20 Jul Mon	Today we learnt about using mails for login & registration. Today I integrated mail sending in already created login and registration pages. using SMTP (Send Mail Transfer Protocol). I created For this I created an app in google account & necessary for sending emails and copy the password of that app and used that account for mail sending using 'nodemailer' package And checked the email sends or not.	By Upgrade the email draft by applying styles in HTML and format the email context according to your purpose. and try bulk email sending.
Day 46 21 Jul Tue	Today we updated the addProduct page and made it better functional & to add multiple products at once using excel file (.xlsx, .xls, .csv). For that we used XLSX package to get excel files as input and then converts the data in json array format and inserted data in table row-by-row to upload bulk-upload the data of products. and also shown our powerBI dashboard to sir.	Suggestions- Add different image locations or paths in sheet for products.

Day 47 22 Jul * Wed	Today we learned about pagination. Instead of showing all results on a single page, display them on number of pages and add navigate to different pages. Implemented pagination for products page.	Implement pagination for view products page and improve styling for navigation.
Day 48 23 Jul Thu	Today, sir gave a task to add search filters like search by product name or category. For this I added two input fields for searching by product name & category and a btn and set that values to use states and passed these values to backend through API (url) and modified the select queries according to it. It almost took whole session time to complete it.	Improve searching functioning and also show related matching results for it.

Day 49

24 Jul

* Fri

Day 50 27 Jul Mon	(updated) Today we fixed previously created ViewProducts page and added update product and delete product option. For update product just sent product id & user_id to backend through API and fire the UPDATE query and set values to provided on that page and then redirects to ViewProduct page again. Then sir gave some advice or suggestions to improve the previously created powerbi dashboard like some provided one.	Upgrade the dashboard UI by applying colors, icons and by formatting.
Day 51 28 Jul Tue	deploying Today we learned our website or webapp on webserver for free on free servers like netlify, cloudflare. We deployed our website through drag & drop and through github repo also.	Deploy your website on both platforms and find ways to deploy backend & database.

Day 52
29 Jul
Wed

Today we learned about how an app is developed at industry with the help of SDLC (Software Development Life Cycle). And started our react + node project development according to this cycle, & ~~final~~ Fixed the database schema for my project. And installed required pkg in project folder.

First create apis and test them using postman.

Day 53
30 Jul
Thu

Today we started developing our projects backend in Node.js. Then I created login and registration endpoints according to my project and tested the user registration is working or not and also applied validations to it and tested the API's again in postman. Also checked the tables in mysql for data is inserted or not. And a new package was used for password encryption called as hash password or bcrypt.

Test the login & registration API's working properly or not.
